# MACHINE LEARNING TUTORIAL I CARLOS III UNIVERSITY

DATA SCIENCE AND ENGINEERING BACHELOR DEGREE

ALEJANDRO PÉREZ, 100429952 CHRISTOPHER MANZANO, 100429927

**APRIL 9TH, 2021** 

# Introduction

Our goal is to create a better agent than the one we created in the first tutorial. To achieve these goals, we will follow the recommendations and instructions given for this project.

This project is divided into three phases. The first one involves translating the environment into states, actions, and rewards. The second phase describes how to implement phase 1 ideas in the *QLearningAgent*. Finally, the third phase contains information related to the performance of our model. We were told that the agents we would train wouldn't be so good, so it's safe to say that this project involved quite a lot of testing to get decent results.

In order to follow the phases and include our insights into the most relevant models, we are going to include subchapters at each phase. Each subchapter at all the phases will refer to a model in specific. They will be of the form 'our n-th approach'.

If you want to read this report in the way we wrote it. You should jump at the end of each phase's subchapter to the next phase's subchapter.

**Remark:** We have implemented some stuff in many files. So we recommend you to execute the program with our files in order to avoid compatibility issues.

Remark: You can play with our plots at the excel file

#### Phase 1: Selection of reward and states

We are going to create a QState class at qState.py which will be a data structure for the states. Then we are going to give some methods our QState instances instead of the gameState instances. That way we consider it will be easier for us to implement changes in the future.

#### Our first approach

As our first approach, we do not want to generate too many states for our q-table since we consider that it will be better to add complexity in advance. We do not have any knowledge about how the agent will perform, thus if we select complex models we could be losing our time because the states may not represent the environment correctly.

Taking this into account, we have considered including the tutorial's one programmed agent. We will introduce the move it would execute in a given moment as a recommended direction. We also are going to include the number of ghosts that are remaining in the labyrinth. Thus we (0-5), where all the states which have 0 will be contained in one final state). Finally have 4x4 + 1 = 17 possible states.

In addition, we have excluded the pac-dots stuff in favor of simplicity. We will add them later in another approach.

Regarding the reward function, we have thought about giving a positive value if it gets closer to the ghost, giving a negative value if it gets far from the ghost, if its distance with the ghost does not change we give 0, and if we eat a ghost we give 5.

#### Go to phase 2

#### Our second approach

The first approach was not a waste of time, to be honest. However, it needed to improve.

In this approach, we are going to remove the number of remaining ghosts as an attribute of our q-state. We have realized that it does not make much difference. We have thought it would be a way of telling our agent when it eats a ghost. But this can be done (and was done) by the reward function.

We also are going to add a new attribute: recommended\_dir2 (0:8) which will consider in which direction the agent should go to reach the zone with the most density of phantoms and ghosts (for instance 0:'Already-Here' 1:'North', 2:'North-West', etc).

As a result of this, we will have 4\*9 =36 states. A q-table is considerably big. But we think it will be worth it.

About the reward function... We consider it is doing fine for now. So we just will add a reward for eating a pacdot.

#### Go to phase 2

# Our third approach

For our third approach, we wanted to try using two programmed agents (from past tutorials) which will give us their recommendations on where Pacman should go. Besides, we need to take into account the pacdots... for this purpose, we will use a recommended zone without the diagonal directions.

Then we should have 4x4x5 states plus a final state which will be when all the ghosts get eaten. These states will be called be:

```
recommended_dir1: {'North', 'South', 'East', 'West'} recommended_dir2:{'North', 'South', 'East', 'West'} recommended zone:{'North', 'South', 'East', 'West', 'Stop'}
```

We are a bit worried about the number of states since we were recommended less than 40. However, we think that the agent will perform well with these states.

# Go to phase 2

# Phase 2: Agent

#### Our first approach

First of all, we are going to create our *QState class*. For now, it will contain, as we discussed earlier, the recommended direction by the tutorial1 agent and the number of remaining ghosts. Which are defined in the constructor.

To define these attributes we created the behavior1(self, gameState) and the countGhosts(self, gameState) methods respectively.

In addition, we included *self.\_\_legalActions*, *getPacmanLegalActions*(*self*) because the QLearningAgent needs it. Also, we included *\_\_getId*(*self*) which will be the one in charge of assigning a number from 1 to 17 at each state according to its attributes. This id will be stored at *self.\_\_id* and will be acceded by the getter *id*(*self*).

Next, we are going to focus on our QLearningAgent.

In the computePosition method, we just made it return the q-state id - 1. At the constructor, we specified the size of the qtable(17). Finally, we copy-pasted our tutorial's 4 update method in this update method.

Respect with to the reward function, we have added as arguments our q-states. This method just contains some conditionals which return the before-mentioned rewards in the given case.

The behavior of our agent is okay with the first two new labyrinths. Also, it does good in open Hunt. It did not perform that well at first, so we started to play with alpha y epsilon. We have found out that an alpha of about 0.5 is good for our agent. Also, a small epsilon was needed. We also needed to increase the rewards by eating a ghost to 100 so they are significant enough.

Also, we have to remark that in the q-table a lot of states are still 0. We consider that the number of ghosts is not that relevant and adds noise to the model. We need to look for other attributes.

#### Go to phase 3

#### Our second approach

Regarding the QLearningAgent we have not made any important changes. We have implemented most of the changes in the QState class. Now It will have the attributes recommended\_dir and recommended\_zone.

Recommended dir stills being the move our tutorial 1 agent would do. In contrast, the recommended zone contains 9 possible outputs which are the directions ('Stop', 'North', 'NorthWest') Pacman should take to go to the zone which has the most populated zone.

For this, we divided all the maps into 4 zones. We will compute the zone in which Pacman is, and the most populated zone by selecting the zone which contains more units. The ghosts are worth 2 units, and the pacdots 1 unit. If Pacman is already in the most populated zone, it will return 'Stop'. If Pacman needs to go in diagonal, it will return a composed direction i.e. 'NorthWest'.

Regarding the \_\_getId method. We modified it so that it could output rows from 0 to 35 since we had 36 states.

At the training phase, it did not seem to improve quite a lot. Even it became worse than our first try. We considered making some changes to the reward function so that it takes into account when the pac dots are eaten. It did not have any effect. The result was the same: Pacman ends up following the recommended direction in all the cases.

We were not able to remove this bias with this approach. Worse than it. It seems we just have increased the noise in our model since it takes longer to learn and ends up doing almost the same thing as our first model.

#### Go to phase 3

#### Our third approach

At the QLearningAgent we have added the method final which is called when the game ends. This method updates the qtable at the final state with the *score x 0.01* as a reward.

Regarding the QSate we had to do some extra work. First of all, we had a lot of problems trying to correctly implement the behavior2 (our second programmed Pacman) since it requires the use of a stack of target directions. If we implemented this method at the QState class we would have an empty stack of target directions at each time we want to get a recommendation since the QStates are created and destroyed at each iteration.

Thus, we implemented a new class called Advisor (at advisor.py) which contains the methods behavior1 and behavior2 (both of our programmed agents). This advisor is created in the constructor of the Class Game to avoid that it gets deleted at iterations. And it is called at every Pacman iteration.

Finally, at the game loop, we assign the attributes recommended\_dir1 and recommended\_dir2 to the gameState class, making it accessible by the QState constructor.

In addition, we have discovered that we could avoid updating the display at the game speeding up the game flow. Thanks to this we were able to train all our agents a lot. And we were able to gather all the statistics we got.

Go to phase 3

#### **Phase 3: Evaluation**

#### Our first approach

We consider that the agent performs relatively well in open maps such as open Hunt and labAA1, 2, 4, 5. But it gets stacked in more complex maps such as classic. We have seen that in classic Pacman gets stacked if the ghosts are static. When the ghosts move randomly it catches them.

We can see that there is a clear inclination in favor of following the recommended direction. So we can say that the agent has learned a policy. We can see also that the most likely decision it will take is south, and the less likely is north.

We think that Pacman is just following the recommended direction. It seems we are biasing our agent, but we think it is a good first approach, we think we could keep the recommended direction by adding a different attribute to our states so it could unbias the model a bit.

# Go to the second approach

# Our second approach

We have tested our agent in the new maps and some of the old maps. It performs worse than our first model. It ended up getting stuck within many maps. It seems it does not learn a clear policy as we can see in the Q Table.

These results show that the recommended\_zone works fine. At the frequency table, we can see that the most frequent state is the one in which the agent is at the recommended zone.

This is reflected in the behavior of the agent which seems to go first to the recommended zone, and then to take into account the recommended direction. However, we think that the racommended\_zone could have fewer states. We could remove the diagonal directions in favor of simplicity.

Go to our third approach

# Our third approach

Another of the drawbacks of having a huge qtable is that it reduces interpretability considerably.

We still can see that recommended\_zone is a very good attribute... The most frequent states are the ones that have stopped as recommended\_zone. And once again we see that the agent tends to go to the recommended zone before taking into account the recommended directions. Even though we can see a possible policy... We do not think we ended up doing any better than in our second approach.

The agent gives more importance to the recommended\_dir1 than the recommended\_dir2 in general. This fact makes us think that recommended\_dir2 is adding noise.

Investigating a little deep in this result we concluded that even though recommended\_dir2 comes from our best-programmed agent it is not a good idea to implement it in the reinforcement learning approach. This agent keeps staking target positions. The agent will recommend the direction to the last target position.

The problem is that in this model, the QLearningAgent will not necessarily go in the target direction. Therefore, the recommended\_dir2 will always point to a target position that nothing has to do with the ghosts or the dots.

We had tried to fix this problem... but the results did not get better.

From the Qtable we get that the most valued action was going east and the less valued is south. (Which makes a lot of sense since in most of the maps Pacman is at the inferior right corner).

Also, we can see that there are states that only got explored 3 times in all the processes. This is a clear indication that we are adding unnecessary complexity to our model.

#### **Our conclusions**

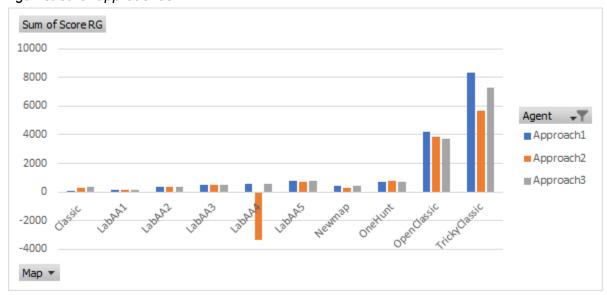

Finally, we are going to compare all the average scores (20 samples) gotten by the three models we have discussed in 10 different maps. We also are going to compare them with two control models. The behavior1-BasicAgentAA (Our first programmed agent) and the RandomPAgent as control metrics.

Our best model is gotten from approach1. So we are going to compare it against the control models. And the other models. If you want to learn more about these results. You can go to the excel file and keep filtering the plots so you can see the information you need. (We have made more diagnostics than these... but we could not put them all together)

We expect that we could do better than the random model, and we hope we get better results than the behavior1 model.

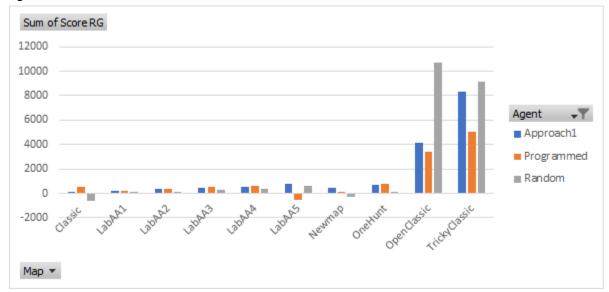

# With Ghost moving randomly:

Against other approaches

We see that Approach one performs better in the layouts with more pacdots, and similarly in the layouts with few pacdots.

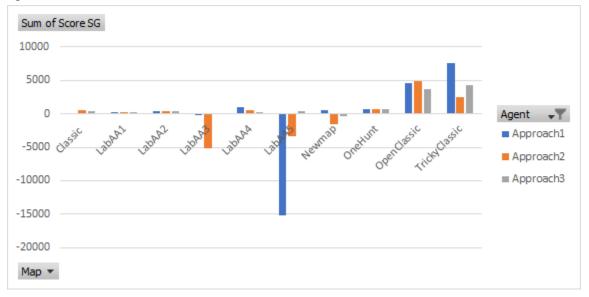

# Against the control models

Here We can see that the Approach1 model does better than the programmed model by a lot in most of the layouts. Also it is curious that the Random Agent does better than approach 1 agent at the layouts with more pacdots.

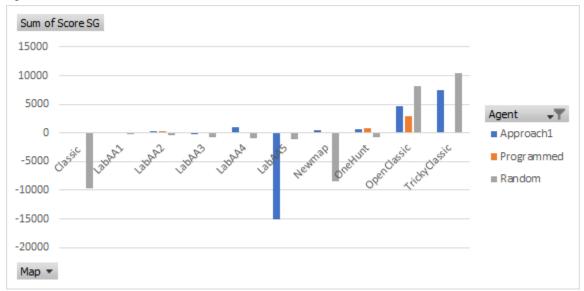

# With Ghost static:

# Against other models

Approach1 does relatively well in most of the layout but in labaa5. On the others, it performs similarly than the other models.

#### Against control models

We can see that there are layouts that the programmed agent could not even finish. Fact, that makes our approach1 model better. Even better than our weka model. The random agent only performs well if there are a lot of pacdots. In other cases it is completely defeated by the approach1 agent.

It is a bit ironic that our best model is the first one we tried. We may have beginner's luck. We were not really sure if the agent improved the performance until we saw these statistics. Approach1 model is clearly better than our programmed agent since it can solve all the maps behavior 1 could not (We remark that bigHunt was not included, that was another difficult map. We do not know whether our agent would perform better on it).

This is a confusing ending, because we improved our programmed agent performance... but we are far away from getting the ideal model (Random Pacman performs better in many cases).

# **Conclusions**

After all our comparisons, we made tests with every approach to figure out which one performed better. To our surprise, our initial approach turned out to be the best one. Approaches 2 and 3 were not bad but far worse than the first one, but had more abstract attributes, like the recommended zone. In a way, our first approach was guilty of overfitting, since it followed our recommended direction for the most part.

#### **General insights**

Throughout the project, we checked how reinforcement learning is not as straightforward as other alternatives, like classification. It is quite clear that the selected attributes are more abstract. Nevertheless, we achieved our goal which was to improve the performance of our first behavior. It performs better in quite a few maps.

#### **Problems encountered**

Our biggest challenge was finding the proper attributes to use in our qtable and defining the best reward function. Sometimes a slight change in the reward function or the attributes made the entire behavior much worse. Furthermore, finding the optimal values for the alpha and epsilon was also quite tricky. After some trial and error, we found the optimal values for these variables, which gave pretty decent results, so that Pac-Man would explore and learn as expected.

#### **Personal comments**

All in all, we must say that these projects tested on the classic Pacman game have been of great help, and have been very fun to play around with. With this second practice, we've learned how to implement glearning to make Pacman teach itself new and even creative ways to win the game. It was a bummer that we couldn't get a cool-looking result, but it was educational nonetheless. For further years, we would strongly suggest that git is used as a way to manage the different assignments and keep track of the changes. We used it and must say it was a life saver:)
